MOTO-MASK WINDSCREEN RAIN COATING

(MMWRC)

Product use guide

1. How does MMWRC work?
 - Water beads will not form on any surface that the coating has been applied to. The coating causes the water beads to spread out, absorbing them into the surface of the invisible film. The water is still there, just spread out onto the surface in an even film that you can see through.
Note: You may notice the coating not sheeting immediately, that is simply the coating trying to absorb more water before the water film evens out.
1. MMWRC can be applied to a dry or wet windscreen.
2. MMWRC can never damage any surface and can easily be applied with just about anything. (e.g. rag, paper towel, old cloth, even newspaper) If any smudging occurs as a result of an “over application” just wipe with a damp towel.
3. You may observe a few smudges on newer windscreens after applications. Simply wipe with a damp rag. The smudging is because the sheeting components can’t penetrate into the surface of the plastic.
4. The older that a windscreen is (the more road miles it has seen), the longer MMWRC will last on the surface of the plastic. Usually the coating will last through a steady rain and typical road mist before needing to be reapplied.
5. What is a “new” windscreen versus an older one?
 - Older windscreens with some road miles on them have seen some dust & grit abrasion on the surface. As a result, the surface is more porous and will “grab” onto to the molecules of the coating better. The molecules will settle into the pores, nooks & crannies. They won’t smudge and last longer.
6. MMWRC can also be applied to goggles and masks to maintain clarity in the rain.
7. MMWRC can also be applied to mirror surfaces to prevent water beads from obstructing the riders view.
8. MMWRC can also be applied to paint to prevent water spotting while riding in the rain.
